**Supplement B.** Nine birds were monitored during the nestling period, between June 15<sup>th</sup> and July 8<sup>th</sup> 2013. GPS sampling frequency was 1 fix/minute. Birds were captured and fitted with data loggers at their nest boxes when they were delivering food to nestlings. All devices were tied dorsally to the base of two central tail feathers. The percentage weight of the devices in relation to tracked Lesser Kestrels was less than 4% for all of the individuals. To download the data from the data-loggers, birds were recaptured at their nest boxes after batteries were exhausted. The deployment of transmitters did not take more than 15 minutes, and on no occasion did it have visible deleterious effects on the studied birds.

Supplement C. Inferential statistics for three diurnal and nocturnal flight attributes of the tracked Lesser Kestrels. As the data points from the same individuals were most likely correlated, leading to pseudo-replication, we used a study design where the averaged night and day activities are compared.

**Supplement D.** Inferential statistics for three nocturnal flight attributes of female and male Lesser Kestrels. As the data points from the same individuals were most likely correlated, leading to pseudo-replication, we used a study design where the averaged nocturnal activities are compared.

**Supplement E.** Inferential statistics for three nocturnal flight attributes of tracked Lesser Kestrels in the two colonies of Gravina in Puglia and Altamura. As the data points from the same individuals were most likely correlated, leading to pseudo-replication, we used a study design where the averaged nocturnal activities are compared.
